

CSE 167:  
Introduction to Computer Graphics  
Lecture #16: Particles, Collisions

Jürgen P. Schulze, Ph.D.  
University of California, San Diego  
Fall Quarter 2020

---

# Particle Systems

# Particle Systems

---

- ▶ Used for:
  - ▶ Fire/sparks
  - ▶ Rain/snow
  - ▶ Water spray
  - ▶ Explosions
  - ▶ Galaxies

# Internal Representation

---

- ▶ Particle system is collection of a number of individual elements (particles)
  - ▶ Controls a set of particles which act autonomously but share some common attributes
- ▶ Particle Emitter: Source of all new particles
  - ▶ 3D point
  - ▶ Polygon mesh: particles' initial velocity vector is normal to surface
- ▶ Particle attributes:
  - ▶ position (3D)
  - ▶ velocity (vector: speed and direction)
  - ▶ color + opacity
  - ▶ lifetime
  - ▶ size
  - ▶ shape
  - ▶ weight

# Dynamic Updates

---

- ▶ Particles change position and/or attributes with time
- ▶ Initial particle attributes often created with random numbers
- ▶ Frame update:
  - ▶ Parameters: simulation of particles, can include collisions with geometry
    - ▶ Forces (gravity, wind, etc) accelerate a particle
    - ▶ Acceleration changes velocity
    - ▶ Velocity changes position
  - ▶ Rendering:
    - ▶ GL\_POINTS
    - ▶ GL\_POINT\_SPRITE
    - ▶ Point shader

# Point Rendering – Vertex Shader

---

```
uniform mat4 u_MVPMatrix;
uniform vec3 u_cameraPos;

// Constants (tweakable):
const float minPointSize = 0.1;
const float maxPointSize = 0.7;
const float maxDistance = 100.0;

void main()
{
    // Calculate point scale based on distance from the viewer
    // to compensate for the fact that gl_PointSize is the point
    // size in rasterized points / pixels.
    float cameraDist = distance(a_position_size.xyz, u_cameraPos);
    float pointScale = 1.0 - (cameraDist / maxDistance);
    pointScale = max(pointScale, minPointSize);
    pointScale = min(pointScale, maxPointSize);

    // Set GL globals and forward the color:
    gl_Position = u_MVPMatrix * vec4(a_position_size.xyz, 1.0);
    gl_PointSize = a_position_size.w * pointScale;
    v_color = a_color;
}
```

# Collision Detection

# Collision Detection

- ▶ **Goals:**
  - ▶ Physically correct simulation of collision of objects
    - ▶ Not covered here
  - ▶ Determine if two objects intersect
- ▶ **Slow calculation because of exponential growth  $O(n^2)$ :**
  - ▶ # collision tests =  $n*(n-1)/2$

# Intersection Testing

---

- ▶ **Purpose:**
  - ▶ Keep moving objects on the ground
  - ▶ Keep moving objects from going through walls, each other, etc.
- ▶ **Goal:**
  - ▶ Believable system, does not have to be physically correct
- ▶ **Priority:**
  - ▶ Computationally inexpensive
- ▶ **Typical approach:**
  - ▶ Spatial partitioning
  - ▶ Object simplified for collision detection by one or a few
    - ▶ Points
    - ▶ Spheres
    - ▶ Axis aligned bounding box (AABB)
  - ▶ Pairwise checks between points/spheres/AABBs and static geometry

# Sweep and Prune Algorithm

---

- ▶ Sorts bounding boxes
- ▶ Not intuitively obvious how to sort bounding boxes in 3-space
- ▶ Dimension reduction approach:
  - ▶ Project each 3-dimensional bounding box onto the x,y and z axes
  - ▶ Find overlaps in 1D: a pair of bounding boxes can overlap if and only if their intervals overlap in all three dimensions
    - ▶ Construct 3 lists, one for each dimension
    - ▶ Each list contains start/end point of intervals corresponding to that dimension
    - ▶ By sorting these lists, we can determine which intervals overlap
    - ▶ Reduce sorting time by keeping sorted lists from previous frame, changing only the interval endpoints

# Collision Map (CM)

---

- ▶ 2D map with information about where objects can go and what happens when they go there
- ▶ Colors indicate different types of locations
- ▶ Map can be computed from 3D model, or hand drawn with paint program
- ▶ Granularity: defines how much area (in object space) one CM pixel represents
